FOREWORD

The study reported herein was performed by the U. S. Army Engineer Waterways Experiment Station (WES) for the Office, Secretary of Defense (OSD), Advanced Research Projects Agency (ARPA), and is a portion of one task of the overall Mobility Environmental Research Study (MERS) sponsored by OSD/ARPA for which the WES was the prime contractor and the U. S. Army Materiel Command (AMC) was the service agent. The broad mission of Project MERS was to determine the effects of the various features of the physical environment on the performance of cross-country ground contact vehicles and to provide therefrom data that can be used to improve both the design and employment of such vehicles. A condition of the project was that the data be interpretable in terms of vehicle requirements for Southeast Asia. The funds employed for this study were allocated to WES through AMC under ARPA Order No. 400. Some funds for preparation and publication of this report were provided by the Development Directorate, AMC, under Department of the Army Project 1-V-O-25001-A-131, Military Evaluation of Geographic Areas. The study was performed during the period June 1964 to November 1965 under the general guidance and supervision of the MERS Branch of the WES, the staff element of WES responsible for the technical management and direction of the MERS program.

This appendix is one of seven to the report entitled An Analytical Model for Predicting Cross-Country Vehicle Performance. These appendixes are:

- A. Instrumentation of Test Vehicles
- B. Vehicle Performance in Lateral and Longitudinal Obstacles (Vegetation)

Volume I: Lateral Obstacles

Volume II: Longitudinal Obstacles

- C. Vehicle Performance in Vertical Obstacles (Surface Geometry)
- D. Performance of Amphibious Vehicles in the Water-Land Interface (Hydrologic Geometry)
- E. Quantification of the Screening Effects of Vegetation on Driver's Vision and Vehicle Speed
- F. Soil-Vehicle Relations on Soft Clay Soils (Surface Composition)
- G. Application of Analytical Model to United States and Thailand Terrains

The study was conducted by personnel of the Area Evaluation Branch, Mobility and Environmental (M&E) Division, under the general supervision of Mr. W. J. Turnbull, Technical Assistant for Soils and Environmental Engineering; Mr. W. G. Shockley, Chief of the M&E Division; Mr. S. J. Knight, Assistant Chief, M&E Division; Mr. A. A. Rula, Chief, MERS Branch; Mr. Warren E. Grabau, Chief, Area Evaluation Branch; and Mr. Jack K. Stoll, Chief, Field Test Section, who was in direct charge of all phases of the study. Personnel of WES technical support elements provided major assistance in the field test program. Data reduction and preparation of plates and tables were accomplished by Messrs. W. T. Willis and V. J. Piazza under the direction of Mr. D. D. Randolph who performed the major portion of the data analysis. This report was written by Messrs. C. A. Blackmon and Randolph.

Directors of the WES during this study and preparation of this report were COL Alex G. Sutton, Jr., CE, and COL John R. Oswalt, Jr., CE. Technical Director was Mr. J. B. Tiffany.

SUMMARY

A total of 372 tests were conducted with one tracked and one wheeled vehicle at the NASA Marshall Space Flight Center, Miss., Eglin Air Force Base, Fla., Pran Buri, Thailand, and Khon Kaen, Thailand. The general purpose of these tests was to obtain data relating characteristics of longitudinal obstacles to vehicle performance in terms suitable for use in developing that portion of the analytical model for cross-country performance. The specific purposes were (a) to determine the maximum horizontal force and total work required to override single standing trees of a range of sizes at various speeds and pushbar heights and (b) to determine average horizontal force and total work required to override trees in multiple array. Empirical relations are presented to support the conclusions that pushbar force required to fail trees singly and in multiple array, work required to fail trees singly and in multiple array, and work required to override a single standing tree may be predicted from stem diameter(s). A method is suggested for predicting work required to override trees in multiple array. The results of the tree-felling tests in the Tunguska meteorite area were confirmed, with a single exception noted, and discussed. It is recommended that additional testing be done in areas of soft soil to determine the effect of soil strength on uprooting, and in grass and brush areas to determine the effect of small vegetation on speed.

AN ANALYTICAL MODEL FOR PREDICTING
CROSS-COUNTRY VEHICLE PERFORMANCE

APPENDIX B: VEHICLE PERFORMANCE IN LATERAL
AND LONGITUDINAL OBSTACLES (VEGETATION)

VOLUME II: LONGITUDINAL OBSTACLES

PART I: INTRODUCTION

Background

1. The main text of this report describes the development of an analytical model for predicting the cross-country performance of a vehicle. The model was based on an energy concept within the framework of classical mechanics that requires cause-and-effect relations be established between discrete terrain factors and vehicle response. This volume of Appendix B deals with the effects of a single terrain factor--longitudinal obstacles. The term "obstacle" in general refers to all features of the terrain, except soil, that are inhibitory to vehicle mobility. The obstacle-effects spectrum on vehicle mobility ranges from complete immobilization to minor speed reduction. For the purpose of the overall study, obstacles were categorized according to the direction of motion forced upon a vehicle negotiating the obstacle, i.e. vertical, lateral, or longitudinal.

2. Vegetation, such as small trees, shrubs, bushes, grasses, etc., that a vehicle can override causes neither vertical nor lateral motion to any marked degree but creates a resisting force parallel to the longitudinal axis of the vehicle that acts to slow the rate of forward motion, hence the nomen longitudinal obstacles.

3. Although very little information has been published on tree override, an empirical relation between felling moment of trees and stem diameter has been published along with some interesting conclusions from tree-felling tests in the Tunguska meteorite area in Russia.

Purpose and Scope

4. This appendix describes the longitudinal obstacle tests conducted

in the United States and in Thailand during the period August 1964-November 1965. The general purpose of these tests was to obtain data relating characteristics of longitudinal obstacles to vehicle performance in terms suitable for use in developing that portion of the analytical model for cross-country performance. The specific purposes were (a) to determine the maximum horizontal force and total work required to override single standing trees of a range of sizes at various speeds and pushbar heights and (b) to determine average horizontal force and total work required to override trees in multiple array.

5. Two types of tests were originally scheduled--single standing tree override and multiple tree override. When it became apparent that bamboo fit neither of these, a third type was added--bamboo clump override.

6. This investigation was limited to trees and bamboo in areas of firm soil.

PART II: TEST PROGRAM

Location and Description of Test Areas

NASA Marshall Space Flight Center

7. Single standing tree override tests and multiple tree override tests were conducted at the NASA Marshall Space Flight Center, Hancock County, Miss. (fig. B1). The locations of the test sites are shown in fig. B2. The test sites were level to gently sloping (less than 2 percent) and free of surface irregularities; grass and some small bushes were growing on the sites (fig. B3). Trees at the sites were coniferous, hardwood, or coniferous and hardwood mixed, with stem diameters ranging from 0.3 to 13.5 in.* Soils in the NASA area were classified as ML, CL-ML, CL, SC-SM, SM-SC, and SP-SM according to the Unified Soil Classification System (USCS). Average cone index in the 0- to 6-in. layer ranged from 80 to 533, and in the 6- to 12-in. layer from 112 to 750.

Eglin Air Force Base

8. Single standing tree override tests and multiple tree override tests were conducted at the Eglin Air Force Base test area, Fort Walton, Fla. (fig. B1). The locations of the test sites are shown in fig. B4. The test sites were level to gently sloping (less than 2 percent), were free of surface irregularities except for an occasional stump hole, and supported grass and abundant small understory plants. Trees at the sites were hardwood or hardwood and coniferous mixed (fig. B5). The stem diameters ranged from 1.0 to 13.0 in. The soils were classified as SM or SP-SM according to the USCS. Cone index in the 0- to 6-in. layer ranged from 41 to 132 and in the 6- to 12-in. layer from 60 to 199.

Pran Buri, Thailand

9. Bamboo clump override tests were conducted at the Pran Buri test area (fig. B6). All the bamboo clump override tests were conducted at one test site about 300 ft square (fig. B7). The test area was level and free of surface irregularities (fig. B8). The stem diameter of the bamboo

* A table of factors for converting British units of measurement to metric units is presented on page ix.

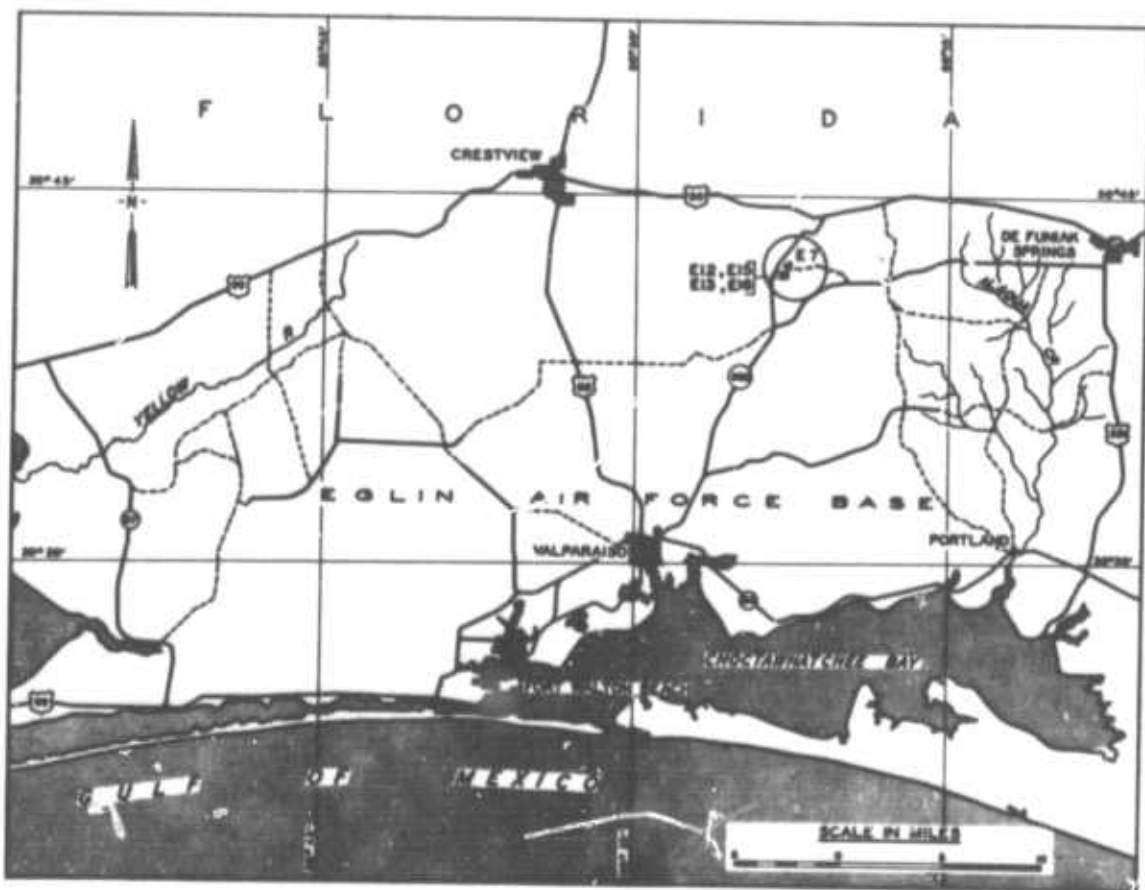

Fig. B4. Location of test sites, Eglin Air Force Base test area

Fig. B5. Eglin Air Force Base test area

ranged from 0.1 to 1.0 in., the clump diameter ranged from 3 to 40 in. at the ground surface, and the number of stems per clump ranged from 10 to 55. The soil was classified as SM in the 0- to 6-in. layer and ML in the 6- to 12-in. layer according to the USCS. The average cone index in the 0- to 6-in. layer ranged from 95 to 174 and in the 6- to 12-in. layer from 112 to 178.

Khon Kaen, Thailand

10. Single standing tree override tests were conducted in the Khon Kaen test area of Thailand (fig. B6). All the tests were conducted at one site about 400 ft square (fig. B7). The test site was level to gently sloping (less than 2 percent), was free of surface irregularities, and supported grass, small broadleaf understory plants, and Heing trees (fig. B9). The stem diameters ranged from 1.8 to 13.0 in. The soil was classified as SM in the 0- to 6-in. layer and as CL-ML in the 6- to 12-in. layer. The cone index ranged from 121 to 209 in the 0- to 6-in. layer and from 120 to 289 in the 6- to 12-in. layer.

Vehicles Used

11. Two vehicles were used in these tests--an M37 3/4-ton cargo truck and an M113 armored personnel carrier. Pertinent physical characteristics of the vehicles are as follows:

M37 3/4-ton cargo truck

Test weight, lb	7350-7645
Tires	
Size	9:00-16
Ply	8
Ground clearance, in.	10.8
Engine	
Type	Gasoline
Brake horsepower	78
Transmission	Manual, synchromesh

M113 armored personnel carrier (APC)

Test weight, lb	19,515-23,896
Track	
Contact length, in.	105
Width, in.	15
Shoe, in.	6
Contact pressure, psi	7.5
Bogies on ground, per side	5
Ground clearance, in.	16.1
Engine	
Type	Gasoline
Brake horsepower	215
Transmission	Hydraulic, single stage multiphase

Photographs of the vehicles are included as figs. B10 and B11.

12. No comparison of the tree-falling capabilities (tree failure is defined in paragraph 32) of the two vehicles used in the investigation was contemplated as the vehicles were considered only as instruments for testing the vegetation. To this end, a heavy-duty pushbar was fabricated and mounted on each vehicle. The pushbar height of the M37 was fixed at 26 in. (fig. B12); the pushbar height of the M113 could be adjusted in 6-in.

Fig. B10. M37 3/4-ton truck

Fig. B11. M113 armored personnel carrier

increments between 20 and 56 in. (fig. B13). Both vehicles were equipped with fairly elaborate measuring and recording systems.*

* This instrumentation is discussed in detail in "An Analytical Model for Predicting Cross-Country Vehicle Performance; Appendix A: Instrumentation of Test Vehicles," by B. O. Benn and M. Keown, Technical Report No. 3-783, July 1967, U. S. Army Engineer Waterways Experiment Station, CE, Vicksburg, Miss.

Fig. B13. Pushbar mounted on M113 armored personnel carrier

Vegetation Tested

13. The vegetation tested consisted of coniferous and hardwood trees, and bamboo grass. Each tree overridden was identified by common name. The conifers included pine and cypress; the hardwoods included oak, hawthorn, and the Heing trees of Thailand. Bamboo grass was treated separately in this investigation.

Types of Tests Conducted

14. Although the tests were basically alike in that they sought the answer to the question "How much force and work are required to override a tree or group of trees, and to what measured physical characteristic of the tree can these be related?", there were some differences in the obstacles per se and the conduct of the tests. The types and number of tests in each of the four areas are listed below. It can be seen that the major effort was devoted to single standing tree override tests (333 tests in three areas).

<u>Location</u>	<u>Single Standing Tree Override</u>	<u>Bamboo Clump Override</u>	<u>Multiple Tree Override</u>	<u>Total</u>
NASA	196	0	12	208
Eglin	78	0	3	81
Pran Buri	0	24	0	24
Khon Kaen	59	0	0	59
	<u> </u>	<u> </u>	<u> </u>	<u> </u>
Total	333	24	15	372

Single standing tree override tests

15. Single standing tree override tests were, as the name implies, conducted against one live standing tree with adjacent trees removed so that the vehicle could approach the tree in a straight line and the tree could fall without interference. These tests were conducted at speeds ranging from 0.0 to 17.1 mph and at five pushbar heights ranging from 20 to 56 in.

Bamboo clump override tests

16. Bamboo clump override tests were conducted against single clumps of bamboo carefully selected so that the vehicle could approach in a straight line and the bamboo clump could fall without interference. These tests were conducted with a single pushbar height (26 in.) and at speeds of approximately 2 mph with the exception of two tests at higher speeds.

Multiple tree override tests

17. Multiple tree override tests were conducted against an array of trees that permitted interference of the crowns as the trees were overridden. An approach strip was cleared so that the vehicle could attain the desired speed before entering the test site. These tests were conducted at approximately 2 mph and at a single pushbar height (26 in.).

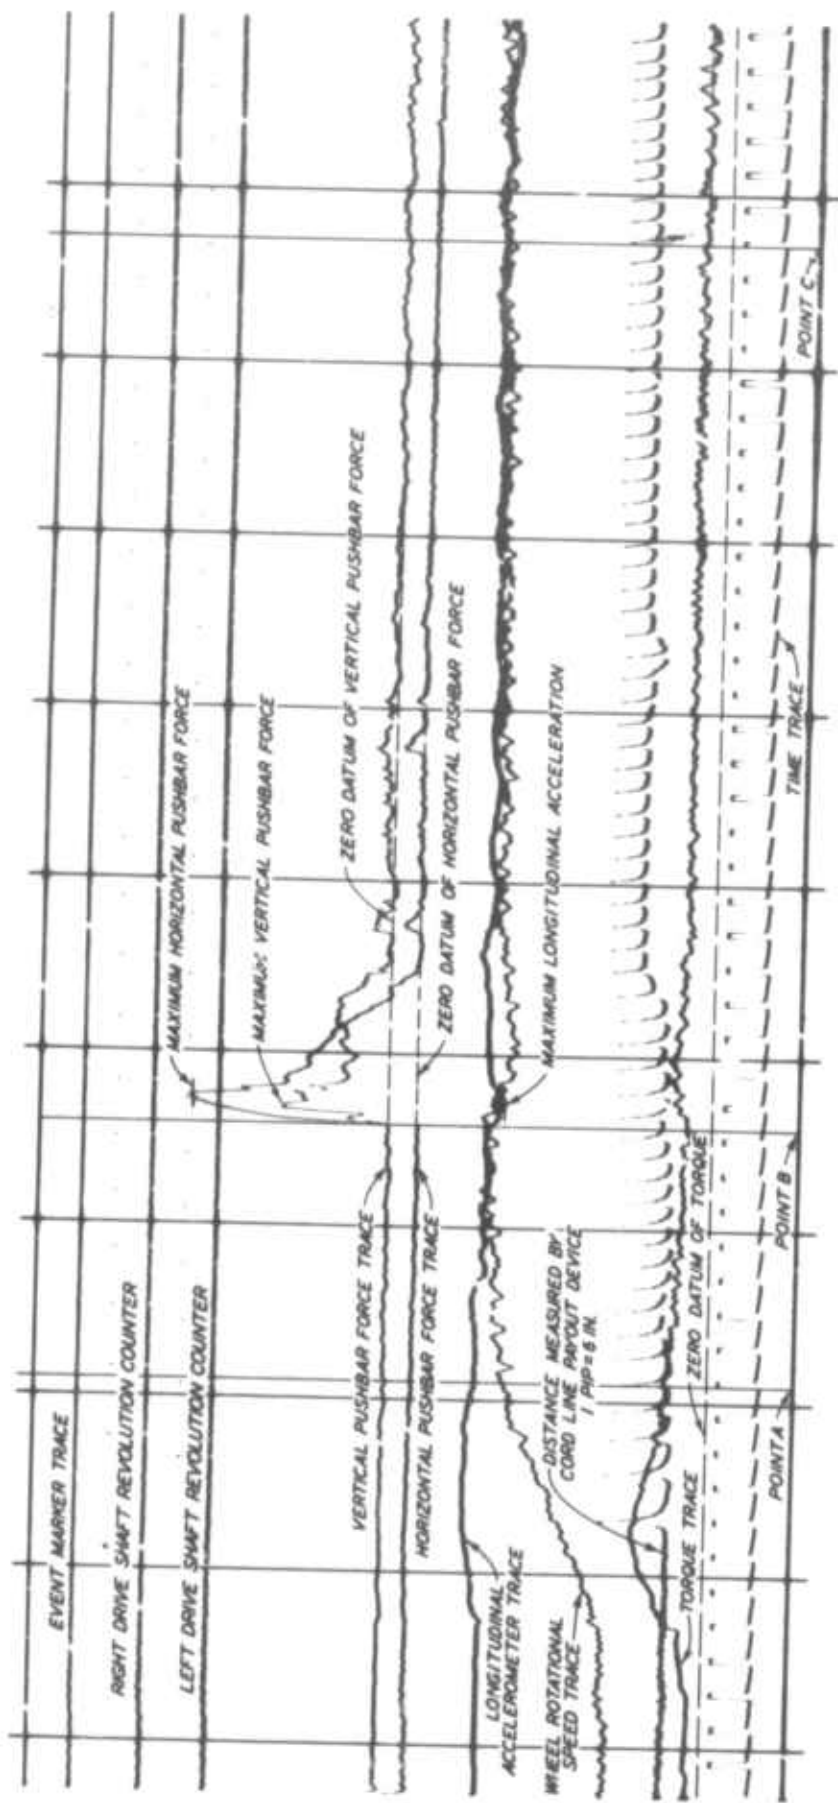

Test Procedures and Data Obtained

Single standing tree override tests

18. Procedures. The vehicle accelerated to the desired contact speed at least 20 ft before striking the tree (fig. B14). The driver

Fig. B14. Pushbar striking tree in single standing tree override test

SCALES

NOTE 1 PIP FROM TRUCK REVOLUTION

SPROCKET ROTATION
1 PIP FROM TIME TRACE = 0.2 SEC

Fig. B15. Oscillogram of single tree override
test 343, vehicle M113

attempted to maintain this speed until the vehicle had completely overridden the tree.

19. Data obtained. By means of electronic instrumentation installed on the test vehicle, continuous measurements of horizontal pushbar force, distance actually traveled, and time were made and recorded. In addition, for some tests vertical pushbar force, drive line torque, drive shaft revolutions, and wheel or track rotational speed and longitudinal acceleration were measured and recorded. An example of an oscillogram record, for test 343, is shown in fig. B15. A summary of the data read directly from the oscillogram, i.e. maximum horizontal pushbar force, maximum vertical pushbar force, and maximum longitudinal acceleration, and the data computed from the oscillogram, i.e. contact speed, work required to fail the tree, work required to override tree, and maximum tractive force is given in table B1.

Bamboo clump override tests

20. Procedures. The vehicle approached the clump at the desired speed and the driver attempted to maintain this speed until the vehicle had overridden the clump (fig. B16).

21. Data obtained. Instrumentation for the bamboo clump override tests was limited to only that needed to determine maximum horizontal pushbar force, work required to fail the clump, vehicle speed, and maximum longitudinal acceleration. A summary of these data is given in table B2.

Multiple tree override tests

22. Procedures. The vehicle approached the test site at a speed of approximately 2 mph in its

Fig. B16. Bamboo clump after being overridden

lowest gear and the driver attempted to maintain this speed while proceeding in as straight a line as possible through the test site overriding all trees in the path of the vehicle (fig. B17). Fig. B18 illustrates a multiple tree override test site after testing.

Fig. B17. Multiple tree
override test. Note
crown interference

Fig. B18. Multiple tree
override test site after
testing

23. Data obtained. The instrumentation on the vehicle measured and recorded horizontal pushbar force, time, distance actually traveled, drive-shaft revolutions, longitudinal acceleration, and drive-line torque. A summary of the data read or computed from the oscillogram is given in table B3.

Vegetation Data Obtained

Single standing trees

24. For convenience in conducting the tests, ensuring that all necessary data were secured, and collating the test data, vegetation data, and soil data, each tree utilized in the single standing tree override tests was given a specific number. For each test the vegetation data consisted of the common name of tree, tree height, branching height, stem diameter at 42 in. aboveground, crown diameter, and mode of failure, and observations of unusual occurrences during the test. These data are given in table B1.

Bamboo clumps

25. Bamboo did not fall in the category of either conifers or hardwoods, and the tests were representative of neither single standing tree override nor multiple tree override. Various vegetation data were obtained during the course of the bamboo clump override investigation; however, only number of stems, stem diameter, and clump diameter are included in this report. These data are summarized in table B2.

Trees in multiple array

26. Vegetation data obtained for the multiple tree override tests included common names of trees, height, stem diameter, structural cell* diameter, and mean tree spacing. A planimetric map of each multiple tree

* The structural cell concept with its derivatives, mean tree spacing, nearest neighbor distance, etc., has been explored with some intensity by the U. S. Army Engineer Waterways Experiment Station. The concept is described in "Quantitative Physiognomic Analysis of the Vegetation of the Florida Everglades," by H. L. Mills, Contract Report No. 3-72, 1963, U. S. Army Engineer Waterways Experiment Station, CE, Vicksburg, Miss.; prepared by Marshall University, Huntington, W. Va.

override test site was prepared; an example is shown in fig. B19. Immediately after each test the number of trees actually overridden was determined. These data are summarized in table B3.

Fig. B19. Planimetric map of multiple tree override, test site NASA 6

Soil Data Obtained

27. During this study the primary reasons for obtaining soil data were to describe the test areas adequately and to ensure that there was no radical change in soil strength or composition at a test site. The effect of soil characteristics on the force required to bend or shear a tree stem appeared nil to the experimenters (possibly because the soils in the test area were firm), and while an effect of soil characteristics on the force required to uproot a tree might be hypothesized, any investigation of such effect was beyond the scope of this study. However, since soil strength and composition are necessary to describe a test area, and for possible, if indeed not probable, future use, the soil data discussed in the following paragraphs are included in this report.

Cone index

28. Cone indexes were measured at the surface and at 3-in. vertical increments to a depth of 30 in. around the base of each tree used in the single standing tree override tests, to a depth of 24 in. around the base

of each bamboo clump, and to a depth of 18 in. along the path of the vehicle in the multiple tree override tests. The average cone indexes for each 6-in. layer are shown in tables B1, B2, and B3, respectively.

Moisture content

29. Average moisture content was determined for the 0- to 6-in., 6- to 12-in., and 12- to 18-in. soil layers for the area around the base of each tree used in the single standing tree override tests. A summary of these data is included in table B1. Moisture content was determined somewhat less frequently for the multiple tree override tests (table B3) and not at all for the bamboo clump override tests.

Soil samples

30. Samples for classification of the soil according to the USCS were obtained from the 0- to 6-in., 6- to 12-in., and 12- to 18-in. soil layers around the base of each tree used in the single standing tree override tests, and from the 0- to 6-in. and 6- to 12-in. soil layers along the path of the vehicle in the multiple tree override tests. A summary of these data is shown in tables B1 and B3, respectively. Because prior reconnaissance had shown the near uniformity of the soil in the area where the bamboo clump override tests were conducted, additional samples for laboratory analysis were not taken at the time of testing. As a matter of record, the USCS soil type in the area of the bamboo clumps is shown below.

<u>Layer</u>	<u>USCS Type</u>	<u>Name</u>
0- to 6-in.	SM	Silty sand
6- to 12-in.	ML	Sandy silt

PART III: ANALYSIS OF DATA

31. The data collected in this test program are analyzed under four headings: Single Standing Tree Override Tests, Bamboo Clump Override Tests, Multiple Tree Override Tests, and Notes, Observations, and Other Data Considered. The conditions and assumptions upon which the analysis is based are described briefly in the following section.

Basis of Analysis

32. From a study of the results of the single standing tree override tests and a study of findings in other programs it was determined that the stem diameter was the tree characteristic that best correlated with the vehicle-tree interaction measurements; hence, stem diameter was selected as the independent variable to represent the tree in the analysis. It was considered that tree failure had occurred when uprooting of the tree, shear of stem, or deformation of the tree terminated the horizontal resistance to the pushbar. Other special considerations peculiar to a particular section of the analysis are discussed in the appropriate section.

Single Standing Tree Override Tests

Maximum horizontal pushbar force

33. Data from the tests of hardwoods and conifers at contact speeds of less than 4 mph and at pushbar heights of 20, 26, 32 and 38, and 56 in. are shown in plates B1, B2, B3, and B4, respectively. The dashed lines in these plates were derived by treating the tree as a cantilever beam. The fiber-stress equation states that the resisting moment at any cross section of a beam is equal to the unit stress (S_m) times the moment of inertia of the cross section with respect to the neutral axis divided by the distance from the neutral axis to the outermost fiber. In applying this equation to a tree, the resisting moment is the product of the horizontal pushbar force and pushbar height ($F_h \cdot h_p$), the moment of inertia of a cross section of a tree stem is $\pi d_s^4/64$, and the distance from the neutral axis to the

outermost fiber is $d_s/2$; the equation can be written as

$$F_h \cdot h_n = \frac{S_m \frac{\pi d_s^4}{64}}{\frac{d_s}{2}} \quad (B1)$$

34. The ultimate unit stress for most of the trees overridden was approximately 7500 psi.* Substituting 7500 psi for the unit stress, the equation is reduced to

$$\text{(For 20-in. pushbar height)} \quad F_h = 36.8d_s^3 \quad (B2)$$

$$\text{(For 26-in. pushbar height)} \quad F_h = 28.3d_s^3 \quad (B3)$$

$$\text{(For 38-in. pushbar height)} \quad F_h = 19.4d_s^3 \quad (B4)$$

$$\text{(For 56-in. pushbar height)} \quad F_h = 13.1d_s^3 \quad (B5)$$

In plates B1-B4 note that although these are not lines of best fit, they do agree with the data points quite well. Two reasons are suggested for the variations:

- a. The 7500-psi unit stress is only an approximate value.
- b. The pushbar height is only an approximation of the length of the moment arm. In more than 50 percent of the tests, the failure occurred in the roots. (See discussion of number and types of failures, paragraph 51.)

35. The solid lines in plates B1-B4 represent the parallel lines of visual best fit. The equations of these curves are

$$\text{(For 20-in. pushbar height)} \quad F_h = 30.0d_s^3 \quad (B6)$$

$$\text{(For 26-in. pushbar height)} \quad F_h = 27.0d_s^3 \quad (B7)$$

* U. S. Department of Agriculture, "Wood Handbook," June 1940, Forest Products Laboratory, Washington, D. C.

$$\text{(For 32- and 38-in. pushbar heights)} \quad F_h = 22.0d_s^3 \quad (B8)$$

$$\text{(For 56-in. pushbar height)} \quad F_h = 15.0d_s^3 \quad (B9)$$

It can be seen in plates B1-B4 that these curves fit the data points slightly better, but it is also apparent that the difference in the two approaches is small.

36. Thus, within the range of conditions tested, on both a rational and an empirical basis, it is apparent that the maximum horizontal pushbar force required to fail a tree can be expressed as a function of stem diameter by the following general equation

$$F_h = Kd_s^3 \quad (B10)$$

where K is a constant for each pushbar height.

37. Data from the tests of single standing trees at vehicle speeds of 4 to 17 mph and pushbar heights of 20 and 38 in. are shown in plate B5. Again, the empirical lines of best fit are shown as solid lines, and the theoretical (slow speed) values for the two pushbar heights are shown by the dashed lines. All but one of the data points fall above the respective theoretical curves, indicating that dynamic factors influence the maximum horizontal pushbar force-speed relation. It is conceivable that additional tests might lead to a "dynamic correction factor" as a function of speed; however, careful examination of the data collected in this program revealed that while there were readily apparent differences between the forces recorded during the tests at less than 4 mph and those recorded at 4 to 17 mph, the tests within each group disclosed no discernible pattern. On this basis it appears that predictions of the maximum horizontal force required to fail a tree at speeds of 4 to 17 mph should be made using the empirical curves.

Work required to fail
a single standing tree

38. The work required to fail a single standing tree (W_p) was computed from the horizontal pushbar force and distance measurements recorded

on the oscillogram and was plotted against the stem diameter of the tree overridden. The results of the tests of coniferous trees in the United States, hardwood trees in the United States, and hardwood trees in Thailand are shown in plates B6, B7, and B8, respectively. Note that a single curve appears to fit the data points on all three of these plots reasonably well. It can be seen that for the range of tree sizes and varieties tested, the work required to fail a single standing tree can be considered independent of tree type or geographical location and can be expressed as a function of stem diameter by the equation

$$W_p = 56.0d_s^3 \quad (B11)$$

Work required to override a single standing tree

39. While the mathematical computations for the total work performed by the pushbar are precise and the relation established is clear, it must be borne in mind that the work performed by the pushbar is only a part of the total work performed by the vehicle. The pushbar, for instance, is unaffected by the frictional drag of vegetation on the undercarriage of the vehicle, and the vehicle obviously does at least a modicum of work in propelling itself, even in the absence of vegetation. To this end, the parameter, "work required to override a single standing tree (W_t)," was defined as the total work done by the vehicle less that amount of work occasioned by motion resistance due to factors other than the tree itself, i.e. slope, soil, grass, etc. The value of this parameter was computed from the torque and distance traces on the oscillogram. The average torque at a constant speed in the approach lane was considered to be necessary to propel the vehicle and was subtracted from the torque recorded while the vehicle was overriding the tree. A plot of work required to override a single standing tree versus stem diameter is shown in plate B9. There is somewhat more scatter on this plot than is desired, but noting that tests from the United States and Thailand, of hardwood and conifers, at speeds less than 4 mph and from 4 to 12 mph are all incorporated, the scatter does not appear excessive. The curve drawn through the data points is parallel to the curve relating work required to fail a single standing tree to stem

diameter, thus permitting the latter value to be converted into work required to override a single standing tree by applying a constant, as follows

$$W_t = 100.0d_s^3 \quad (B12)$$

$$W_t = 1.786W_p \quad (B13)$$

Distance required to fail a single standing tree

40. All attempts to relate vehicle travel distance required to fail a single standing tree with tree characteristics, force measurements, or pushbar heights were unsuccessful. A summary of the distances the vehicles traveled to fail trees with the pushbar at heights of 20, 26, and 32 in. is given in table B4. From the table it can be seen that with a 20-in.-high pushbar the distance required to fail a single standing tree ranged from 2.1 to 9.4 ft, and the average distance was 5.67 ft; with a 26-in.-high pushbar the distances ranged from 3.5 to 8.2 ft and the average distance was 5.71 ft; and with a 32-in.-high pushbar the distances ranged from 3.0 to 8.7 ft and the average distance was 5.93 ft. The small increase in average distance as the pushbar height was increased from 20 to 32 in. is judged to be insignificant. Since the height of the bumper or leading edge of nearly all military vehicles falls within the 20- to 32-in. range, the average distance required to fail a tree with a military vehicle is considered to be the average of all tests or about 5.8 ft.

Bamboo Override Tests

41. Although a bamboo clump might appear, superficially at least, to be either a special case of a single standing tree or a multiple array of small trees, the test results were not compatible with those of either category. Plots of maximum horizontal pushbar force and pushbar work versus stem diameter, number of stems, clump diameter, and various combinations were studied to determine which feature of the bamboo clump would

give the best correlations. It was found that the plots with clump diameter as the independent variable yielded the least scatter; this is not unreasonable when it is considered that in all tests the bamboo clumps failed by uprooting, as previously illustrated (fig. B16, page B17).

42. The M37 truck became immobilized in four of the 24 bamboo override tests. In each of these four tests, the bamboo clump was actually failed, but when the vehicle attempted to completely override the clump at a slow speed, the front wheels of the vehicle were lifted clear of the ground and there was insufficient traction for the rear wheels to furnish the necessary forward thrust. In other tests, considerable wheel slip occurred as the vehicle was overriding the tree, resulting in torque measurements that were not amenable to analysis, hence the analysis is limited to maximum horizontal pushbar force required to fail a bamboo clump and work required to fail a bamboo clump as functions of clump diameter. The relations obtained are discussed in the following paragraphs.

Maximum horizontal pushbar force

43. A plot of the maximum horizontal pushbar force (F_h) required to fail a bamboo clump versus clump diameter is given in plate B10. The data from the four tests in which immobilization occurred are shown by closed symbols and are believed to be valid points on this plot since the immobilizations occurred after the pushbar had failed the clump. The curve drawn represents the line of visual best fit without reference to the data point from test 246. Notably, this test was conducted at the lowest speed and the bamboo clump overridden had the fewest stems of any in the program. This seems to point out that factors other than clump diameter, i.e. number of stems, speed of impact, and stem diameter, may significantly affect the maximum horizontal pushbar force. However, for the tests conducted, the equation of the curve in plate B10

$$F_h = 2.1d_c^{2.15} \quad (B14)$$

represents a reasonable approximation of the force required to fail a bamboo clump.

Work required to fail a bamboo clump

44. As previously stated, the attempts to secure torque measurements during the bamboo clump override tests were not remunerative; hence, the work required to override a bamboo clump could not be determined from the available data. Nevertheless, the intermediate value, work required to fail a bamboo clump (W_b), was studied and a plot of these values versus clump diameter is shown in plate B11. The data from the tests resulting in immobilizations are shown by closed symbols and are held to be valid points. The curve drawn is the line of best visual fit, again without reference to test 246. The scatter of the data is less than that on the plot of horizontal pushbar force versus clump diameter, suggesting that work required to fail the clump is less affected by speed than is horizontal pushbar force. The equation of the curve in plate B11

$$W_b = 3.41d_c^{2.15} \quad (B15)$$

provides an acceptable method of predicting the work required to fail a bamboo clump within the range of sizes tested.

Multiple Tree Override Tests

45. Obviously it takes more effort to override trees spaced closely together than when each tree can fall free of interference by its neighbors. The increase is due principally to the interference of crowns as shown in fig. B18, page B18. The study of this increase was the principal purpose of the multiple tree override tests.

Average horizontal pushbar force

46. A plot of average measured horizontal pushbar force required to fail trees in multiple array (F_m) versus the average horizontal pushbar force that would have been required to fail the same combination of trees severally (F_g) as computed from the relations established in the single standing tree override tests is shown in plate B12. A sample computation of average pushbar force required for test 12 is shown as follows.

Distance ft	Tree No.	Stem Diameter (d_s), in.	Work Required to Fail Tree (W_p), lb-ft
25	85	5.7	10,371
	86	3.5	2,401
	103	3.1	1,668
	104	5.9	11,501
	105	3.6	2,613
	108	6.1	12,711
	109	4.2	4,149
Total			45,414

$$F_s = \frac{45,414}{25} = 1817 \text{ lb}$$

It can be seen in plate B12 that the average force requirement for trees in multiple array was significantly greater than that required to fail the trees severally, even when the latter was as low as 136 lb. It can also be seen that the increase in average force required becomes greater as the computed average force required to fail the trees separately increases. The scatter of data appears well within the limit of experimental error and the equation given in this plot

$$F_m = 0.66F_s^{1.127} \quad (\text{B16})$$

appears to adequately define the average horizontal force demand of trees in multiple array within the limits encountered in this test program.

Work required to fail
trees in multiple array

47. A plot of measured work required to fail trees in multiple array (W_m) versus the summation of the work required to fail the same combination of trees severally as computed from relations developed in single standing tree override tests is shown in plate B13. In this plot it can be seen that the total measured work required to fail trees in multiple array was significantly greater than the total work required to fail the same combination of trees severally, and that the increase in work required by trees in multiple array became greater as the computed work required increased.

Again, the scatter of data appears quite reasonable and the equation given in this plate

$$W_m = 0.6 \left[\sum_{1 \rightarrow n} (W_p) \right]^{1.088} \quad (B17)$$

satisfactorily expresses the relation between work required to fail trees in multiple array and the summation of the work required to fail the same combination of trees individually.

48. Since the work required to fail a single standing tree (W_p in the equation above) has been shown to be a function of the stem diameter, combining equation B11 and equation B17 gives

$$W_m = 0.6 \left[\sum_{1 \rightarrow n} (56d_s^3) \right]^{1.088} \quad (B18)$$

thus expressing work required to fail trees in multiple array as an exponential function of the stem diameters.

Work required to override trees in multiple array

49. The work required to override trees in multiple array is, of course, greater than the work required to fail trees in multiple array for the same reasons that applied to single standing trees. Regrettably, the available data do not permit an empirical evaluation of the work required to override trees in multiple array. Torque meters were not available until late in the test program. Therefore, torque measurements were obtained only for tests 455, 458, and 459. However, because of wheel slip during the test and errors made in calibrations, the torque measurements were not reliable. Nevertheless, it is possible to make some inferences from the relations established herein.

50. It has been shown that the work required to override a single standing tree expressed as a function of the stem diameter (equation B12) is linearly related to the work required to fail a single standing tree expressed as a function of the stem diameter (equation B11), and may be equally as well expressed as a constant times the work required to fail a single standing tree (equation B13). In the absence of data indicating

otherwise, it appears that the same constant might be used to relate work required to fail trees in multiple array to work required to override trees in multiple array (W_o); then

$$W_o = 1.786W_m \quad (B19)$$

and substituting in equation B18 and reducing

$$W_o = 1.07 \left[\sum_{1 \rightarrow n} (56d_s^3) \right]^{1.088} \quad (B20)$$

Notes, Observations, and Other Data Considered

Tree failure modes

51. Illustrated in fig. B20 are the five tree failure modes exhibited in the override tests: type 1, in which the stem failed in compression; type 2, in which the stem failed in tension; type 3, in which the roots failed in tension and the soil in shear; type 4, in which the roots failed in tension without pronounced failure of the soil; and type 5, in which the stem deformed elastically. Types 1, 2, and 5 indicate that the root-soil system was stronger than the stem. Types 3 and 4 indicate that the stem was stronger than the root-soil system. The number of failures of each type is given in the following tabulation:

<u>Type</u>	<u>No. of Failures</u>
0 No failure indicated	11
1 Compression (stem)	10
2 Tension (stem)	37
3 Shear (soil) and tension (root)	215
4 Tension (root)	12
5 Elastic (stem)	41

There was no apparent indication that the type of failure, per se, significantly affected the test results.

a. Type 1, compression (stem)

b. Type 2, tension (stem)

c. Type 3, tension (root)
and shear (soil)

d. Type 4, tension (root)

e. Type 5, elastic (stem)

Fig. B20. Tree failure modes

Effect of soil conditions

52. Within the range of soil conditions encountered in this program, the effects of the soil type, soil strength, or moisture content could not be isolated. While it is believed that the method of analysis, i.e. push-bar force and torque minus motion resistance, satisfactorily eliminated or compensated for soil conditions insofar as the vehicle was concerned, there remains the fact that 215 single standing tree override tests, as shown in the preceding tabulation, resulted in soil shear and all of the bamboo clump override tests resulted in soil shear. It is axiomatic that soil shear strength varies inversely with moisture content, and it would be reasonable to expect the soil condition to have a significant effect on force required to fail or override a tree when the failure occurred in the soil. For instance, the tabulation in the following paragraph indicates a considerable difference in felling moments in dry and moist soils in the Tunguska Meteorite Area; however, as previously stated, the test areas used in the program reported herein were chosen to minimize the effect of soil strength on the vehicle, i.e. no significant rutting. It might be reasoned that when the soil is sufficiently strong, an increase in strength does not result in a significant increase in vehicle performance; then the increase in resistance to uprooting a tree would also be insignificant. This is, however, beyond the scope of this test program.

Data from other sources

53. In a report of the preliminary results from the 1961 combined Tunguska Meteorite Expedition, Florenskii* described a series of tests in which the felling moment of trees was determined by means of a winch and a dynamometer. Results of these tests yielded the following conclusions: (a) there is no relation between felling moment and species and age of a tree, (b) there is a distinct relation between moment and tree diameter, analytically nicely described by a parabola, (c) the parabolas are completely identical for fine and rocky soils, (d) the scatter of the data diminishes in inverse proportion to the diameter of the tree, (e) the felling moments of trees in dry soils are significantly greater than the

* K. P. Florenskii, "Preliminary Results from the 1961 Combined Tunguska Meteorite Expedition," Meteoritica, Vol XXIII, Moscow, 1963.

felling moments of trees in moist, riverside soils. Each of the first four conclusions was verified by single tree override tests conducted in the United States and in Thailand. Florenskii's fifth conclusion could neither be confirmed nor denied; however, the magnitude of variation he reported is interesting and is summarized in the following tabulation.

Tree Diameter in.	Average Felling Moment, lb-ft		
	Moist Soil	Dry Soil	Percent Increase
5.9	5,100	8,000	57
7.9	10,800	16,600	54
9.8	20,200	26,700	37
11.8	30,400	39,800	31

PART IV: CONCLUSIONS AND RECOMMENDATIONS

Conclusions

54. Based on the analysis of the data reported herein, and subject to the limits imposed by these data, the following conclusions are offered:

- a. The maximum horizontal pushbar force required to fail a single standing tree may be predicted from the stem diameter, vehicle speed, and pushbar height (paragraphs 33-36).
- b. The work required to fail a single standing tree may be predicted from the stem diameter (paragraph 38).
- c. The work required to override a single standing tree may be predicted from the stem diameter (paragraph 39).
- d. The average horizontal pushbar force required to fail trees in multiple array may be predicted from the stem diameter (paragraph 46).
- e. The work required to fail trees in multiple array may be predicted from the stem diameter (paragraphs 47-48).
- f. The maximum horizontal pushbar force required to fail a bamboo clump may be predicted from clump diameter (paragraph 43).
- g. The work required to fail a bamboo clump may be predicted from stem diameter (paragraph 44).

Recommendations

55. It is recommended that:

- a. Additional single standing tree override tests be conducted in areas of low soil strength to determine the effect, if any, of soil strength on the force required to uproot a tree.
- b. Additional multiple tree override tests be performed to extend the relations already developed and to develop empirically the relation of work required to override trees in multiple array and stem diameters.
- c. Both single vegetation stem override tests and multiple vegetation stem override tests be conducted in areas of grass and brush to develop override-speed relations.
- d. Additional bamboo override tests be performed in other areas with a vehicle capable of completely overriding the bamboo clumps.

13. ABSTRACT

A total of 372 tests were conducted with one tracked and one wheeled vehicle at the NASA Marshall Space Flight Center, Miss., Eglin Air Force Base, Fla., Phan Buri, Thailand, and Khon Kaen, Thailand. The general purpose of these tests was to obtain data relating characteristics of longitudinal obstacles to vehicle performance in terms suitable for use in developing that portion of the analytical model for cross-country performance.⁽¹⁾ The specific purposes were (a) to determine the maximum horizontal force and total work required to override single standing trees of a range of sizes at various speeds and pushbar heights and (b) to determine average horizontal force and total work required to override trees in multiple array. Empirical relations are presented to support the conclusions that pushbar force required to fall trees singly and in multiple array, work required to fall trees singly and in multiple array, and work required to override a single standing tree may be predicted from stem diameter(s). A method is suggested for predicting work required to override trees in multiple array. The results of the tree-felling tests in the Tunguska meteorite area were confirmed, with a single exception noted, and discussed. It is recommended that additional testing be done in areas of soft soil to determine the effect of soil strength on uprooting, and in grass and brush areas to determine the effect of small vegetation on speed.
